

AI SOC Incident Report

Destination Port: 443

Flow Duration: 117556753

Prediction: Suspicious

Risk Level: ■ Low

AI Threat Explanation

Here's the analysis: 1. **Threat Summary:** A suspicious, extremely long-duration (over 32 hours) HTTPS flow (port 443) has been detected. This prolonged connection can signify persistent Command and Control (C2) communication, slow data exfiltration, or a backdoor connection from a compromised host, disguised as legitimate web traffic. 2. **Why it is suspicious:** The flow duration of 117,556,753 milliseconds (approximately 32.6 hours) is highly atypical for standard web browsing sessions. Such an extended period strongly suggests a non-interactive, persistent communication channel often leveraged by malware for C2 beaconing or covert data transfer. 3. **Risk Level:** ■ Low (as per system prediction). 4. **Recommended Action:** Initiate an immediate, in-depth investigation of both the source and destination endpoints. Examine endpoint logs for unusual processes, network connections, and data transfer volumes. Analyze surrounding network traffic. Isolate the affected host if compromise is confirmed.
